

## Python Basics for Data Science

### Module 4: Working with Data in Python

Class or Method	Description	Example
<code>close()</code>	Closes a file.	<code>file1.close()</code>
<code>dot</code>	Calculate the dot product from two NumPy arrays.	<code>np.dot(U, V)</code>
<code>dtype</code>	Check the type of values stored in a NumPy array.	<code>myArray.dtype</code>
<code>linspace()</code>	Returns evenly spaced numbers over a specified interval.	<code>np.linspace(-2, 2, 5)</code>
<code>matplotlib.pyplot</code>	A library of functions that make matplotlib behave similar to MATLAB.	<pre>import matplotlib.pyplot as plt plt.plot([1, 2, 3, 4]) plt.xlabel("time") plt.ylabel("distance") plt.show()</pre>
<code>max</code>	Get the largest value from a NumPy array.	<code>myArray.max</code>
<code>mean</code>	Get the mean of a NumPy array.	<code>myArray.mean</code>
<code>ndim</code>	Get the number of dimensions of a NumPy array.	<code>myArray.ndim</code>
<code>numPy</code>	A library used for working with arrays as well as functions for working with linear algebra, matrices, and Fourier transform.	<code>import numpy as np</code>
<code>open()</code>	Opens a file.	<code>file1=open(example1, "r")</code>
<code>pi</code>	The value of pi.	<code>np.pi</code>
<code>read()</code>	Reads a file.	<code>FileContent=file1.read()</code>
<code>readline()</code>	Reads the first line of the file.	<code>with open(example1, "r") as file1:</code>

		<pre>print("first line: " + file1.readline())</pre>
<b>shape</b>	A tuple of integers that indicates the size of a NumPy array in each dimension.	<pre>myArray.shape</pre>
<b>sin()</b>	Calculate the sine of all elements in a NumPy array.	<pre>y=np.sin(x)</pre>
<b>size</b>	Get the size of a NumPy array.	<pre>myArray.size</pre>
<b>std</b>	Get the standard deviation of a NumPy array.	<pre>myArray.std</pre>
<b>T</b>	Transpose a NumPy array.	<pre>my2DArray.T</pre>
<b>with open() as</b>	Opening a file using the keyword "with" automatically closes the file after the code in the with statement is executed.	<pre>with open(example1, "r") as file1:     FileContent = file1.read()     print(FileContent)</pre>
<b>write()</b>	Writes a line to a file. write() takes two arguments, the pathname/URL and a mode. Passing the parameter 'w' as the mode overwrites all existing data. Passing 'a' as the mode appends the data.	<pre>exmp2 = '/resources/data/Example2.txt' with open(exmp2, 'w') as writefile:     writefile.write("This is line A")</pre>
